(54) Title: METHOD FOR THE RAPID DETERMINATION OF BACTERIA

(57) Abstract

The invention relates to the detection, identification and diagnosis of bacteria in samples in general and in particular in clinical samples such as blood, urine, saliva, cerebrospinal fluid that are taken from patients that are possibly infected with a, as yet, unknown, possibly pathogenic bacterium, or during follow–up diagnostic testing to, for example, evaluate therapeutic measures that have been taken so far to treat the disease. The invention provides a method for detecting or identifying a bacterium suspected of being present in a sample comprising testing said sample by Gram–staining and testing said sample with a probe according to an *in situ* hybridisation protocol selected on the basis of the outcome of said Gram–staining. The invention also provides probes for use in said method.

Title: METHOD FOR THE RAPID DETERMINATION OF BACTERIA

The invention relates to the detection, identification or determination of bacteria in samples in general and in particular in clinical samples such as blood, urine, saliva, cerebrospinial fluid, faeces, pus and tissue that are taken from patients that are possibly infected with a, as yet unknown, possibly pathogenic bacterium, or during follow-up diagnostic testing to for example evaluate therapeutic measures that have been taken so far to treat the disease.

Traditional methods to determine or identify bacteria in general start with a Gram-stain, which is well known in the art. Such a stain can be performed on a sample immediately after sampling or, when not enough bacteria are present, after a short period of culturing of the sample. In general, four types of bacteria are found after Gram-staining; Gram-negative rods and cocci and Gram-positive rods and cocci. However, such a Gram-stain can only in very exceptional cases provide the clinician with the knowledge required to provide accurate therapy.

Examples of Gram-negative rods in clinical samples are *Enterobacter, Klebsiella, Salmonella, Escherichia, Proteus* and *Pseudomonas species*, of Gram-negative cocci are *Neisseria species*. Gram-positive rods that may be found in clinical samples are *Bacillus species*, of Gram-positive cocci are *Enterococcus, Streptococcus* and *Staphylococcus species*. Some of these, such as *Streptoccus* and *Staphylococcus* can easily be further determined or distinguished from each other by their morphological characteristics. Streptococci (and Enterococci) are

Streptococcus species cannot be distinguished by morphology alone. However, such a distinction on a genus level cannot be considered satisfactory for clinical purposes and consequently further identification is required to administer proper medication. For example in the case of Staphylococcus, these bacteria need to be further distinguished based on their coagulase positive (S. aureus) or coagulase negative (S. haemolyticus and others) character because these two groups require different antibiotic therapy.

In general, the exact species involved is determined by culturing techniques. To fully determine the species of a bacterium present in a clinical sample the following steps are in general required:

- (1) Pre-culturing of the sample in order to amplify the number of bacteria to a level above the lower detection limits of step (2).

- (2) Culturing on selective and non-selective media.

These traditional methods are time consuming. On average, a regular diagnostic procedure takes at least a few hours (minimally 2) of pre-culturing followed by minimally 24 hours of culturing on selective and non-selective media. This implies that it takes at least 26 hours before the clinician obtains a diagnosis on which he or she can select appropriate antibiotics or base other further treatment.

The latency-period between the admittance of a patient and the final diagnosis in most cases is critical for the treatment and the speed-of-recovery of the patient. During this latency-period a patient is in general treated with broad-spectrum antibiotics. The antibiotic of choice is mainly determined by the "clinical eye" of the clinician.

By selecting a broad-spectrum antibiotic, such

is affected also. This side-effect heavily decreases the patients defence against microbial invaders from the environment. Especially the lowering of the colonisation resistance in the gastro-intestinal tract may cause severe overgrowth by e.g. yeasts and fungi. The resulting secondary infection, or super-infection, in septicaemic patients who already suffer from a decreased immunity often leads to life-threatening situations.

Apart from the serious danger to the patient's health, wide-spectrum antibiotic therapy poses another threat. The repeated exposure of indigenous bacteria to antibiotics enhances the emergence of resistance against such an antibiotic. Especially when a resistance-gene is encoded on a plasmid, other (potential pathogenic) bacterial species may become resistant after the uptake of the plasmid. This latter scenario is considered to be a major problem in hospital epidemiology. It is therefor of paramount therapeutic and epidemiological importance to speed up the methodological procedures in the diagnosis of blood samples from for example septicaemic patients to be able to select specific antibiotic therapy designed for the specific pathogen found, thereby refraining from using broad-spectrum antibiotics.

Present techniques other than culturing, albeit in general specific when beforehand knowledge exists about the species involved, cannot be used with samples containing uncharacterised species, and do thus not fit the acute needs when speedy diagnosis is needed on uncharacterised patient material. In general, these methods are also too slow to meet the needs of the clinician in providing cure to his or her patients. Most, for example, require isolation of nucleic acid, or amplification of nucleic acid, or both, before the actual

identify the pathogen and rapidly select the antibiotic against which the pathogen is not resistant. To do this, the micro-organism would again have to be cultured, to determine its resistance pattern, thereby again introducing a lag in diagnosis.

In short, there is a need for fast and reliable diagnosis of bacteria, present in for example clinical samples that may replace or add to the currently used culturing techniques.

The invention provides a method for determining, detecting or identifying a bacterium suspected of being present in a sample comprising

a) testing said sample by Gram-staining and

b) testing said sample with a probe according to an *in situ* hybridisation protocol selected on the basis of the outcome of said Gram-staining.

Rapid techniques for detecting bacteria and other bacteria in general are known. For example, *in situ* hybridisation is a well known technique, however, in general it has only been applied in specialised laboratories as a tool to detect and quantify the relative abundance of bacteria that are difficult to culture using traditional methodology or as a tool to quantify for example growth kinetics of already known bacteria in culture.

In short, in *in situ* hybridisation, nucleic acid probes, labelled with a reporter molecule such as an enzyme or a fluorescing substance, are reacted with specific nucleic acid sequences found specifically and preferably solely in the bacteria under study, which for this purpose has been permeabilised to let the probe enter the organism. As target sequence multiple copies of

23S ribosomal RNA, mitochondrial RNA, messenger RNA and nuclear DNA.

In situ hybridisation has never been successfully applied for rapid detection of bacteria in clinical samples because the presently used in situ hybridisation techniques are too inaccurate and too slow to give an advantage over traditional culturing.

First of all, hybridisation requires permeabilisation of the pathogen, and until now no generally applicable permeabilisation protocols have been developed that allow sufficient but restricted lysis of many or all of a broad range of unidentified bacteria. In general, mild permeabilisation leaves many bacteria (such as *Staphylococcus spec.*) inaccessible for subsequent hybridisation with probes, whereas rigorous permeabilisation often fully lyses most bacteria, thereby foregoing the possibility to detect them all together.

In addition, current protocols are in general time-consuming multi-step procedures; hybridisation often requires minimally 24 hours, thereby giving no relief to the needs of the clinician who is only helped with accurate and speedy diagnosis. Furthermore, they mostly require beforehand knowledge about the genus or even species involved in order to select appropriate probes; having such beforehand knowledge is clearly not the case in the event of a patient having an unidentified infection. Also, the present, already inappropriate hybridisation techniques do not allow to gather information on the response against antibiotics of the bacterium involved.

The invention provides a fast and reliable method for diagnosis, detection and/or determination of bacteria which may be present in a sample. Such a sample may be a

from a (contaminated) bacterial culture, or drinking water or food suspected to be contaminated with a bacterium.

In a preferred embodiment the invention provides a method to detect or identify a bacterium suspected of being present in a clinical sample. Herein, the term "clinical sample" comprises a sample obtained or derived from an animal, preferably a mammal, more preferably a human being. Such a sample may be sampled or tested because a bacterial infection or disease is suspected. Such a sample can be of various origin, such as blood, serum, white blood cells, cerebrospinal fluid, synovial fluid, tissue, biopsies, urine, saliva, faeces, and others. In a preferred embodiment the invention provides a method wherein said sample is mammalian blood, preferably being derived from a human.

A sample can be a primary sample or it can be a secondary or sub-sample which is derived from a primary sample by diluting, splitting or culturing it one or more times. Diluting allows determining the relative abundance of a bacterium in a sample, thereby thus providing a method allowing not only qualitative but also quantitative determination of a bacterium. A sample can be tested directly after it has been obtained or after it has been stored, for example by cooling or freezing and secondary or sub-samples can be tested in parallel or subsequent from each other.

The invention provides a method for typing by determining by Gram-staining the Gram-positive or Gram-negative and rod or coccus type of bacterium in a clinical sample and further testing said sample according to an in situ hybridisation protocol selected on the basis of the outcome of said Gram-staining. A primary advantage of a method according to the invention is the speed with which

protocols. For example, Gram-positive streptococci can now be determined true within about 2 - 3 minutes, Gram-negative rods from within about 45-60 minutes, if needed, whereas traditional protocols often need a working day or more. In top of that, after a first indication, or even a definitive selection, of a preferred antibiotic for therapy can be given, based on the results of the testing.

A preferred embodiment of the invention is a method for the detection or identification of bacteria in a clinical sample of blood of patients who are suspected to suffer from a septicaemia. In a preferred embodiment a method provided by the invention makes use of labeled probes, such as fluorescently labeled single strain DNA-, RNA- or PNA-probes, directed against specific target sequences on for example the ribosomal RNA of the target bacterium present in the sample.

The invention provides a method wherein classical Gram-staining indicates the presence of a Gram-negative or Gram-positive bacterium in said sample, further comprising determining the rod or coccus character of said bacterium, thereby establishing the subsequent testing protocol.

When a Gram-negative bacterium is of the rod type, the invention provides a method further comprising hybridising said sample with at least one probe selected from a group of probes capable of hybridising with nucleic acid found in *Escherichia coli*, in *Klebsiella pneumoniae*, in *Klebsiella oxytoca*, in *Serratia marcescens*, in *Enterobacter aerogenes*, in *Proteus mirabilis*, in *Proteus vulgaris*, in *Proteus morganii*, in *Salmonella typhi*, in *Pseudomonas aeruginosa*.

Furthermore, the invention provides a method wherein said character is of the Gram-positive coccus type, further comprising subjecting said sample to treatment

comprising determining the rod or coccus character of said bacterium, and when said Gram-positive character is of the rod type, further comprising subjecting said sample to treatment with a lysis buffer comprising lysozyme and/or Proteinase K.

In addition, when said character is of the Gram-positive coccus type, a method is provided further comprising determining a chain-like or clump-like character of said bacteria before a hybridisation protocol is selected. When before mentioned character is chain-like, a method provided by the invention is further comprising subjecting said sample to treatment with a lysis buffer comprising lysozyme, and further comprising hybridising said sample with at least one probe selected from a group of probes capable of hybridising with nucleic acid found in *Enterococcus faecalis*, in *Streptococcus pneumoniae*, in *Streptococcus mitis*, in *Streptococcus viridans*, in *Streptococcus sanguis*, in *Enterococcus faecium*.

In addition, a method is provided wherein said character is clump-like, further comprising subjecting said sample to treatment with a lysis buffer comprising lysostaphin and or Proteinase K, further comprising hybridising said sample with at least one probe selected from a group of probes capable of hybridising with nucleic acid found in *Staphylococcus aureus*, in *Staphylococcus haemolyticus*, in *Staphylococcus saprophyticus*.

Probes used in a method as provided by the invention can be directed against various target nucleic acid molecules found in a bacterium which can be used are for example ribosomal RNA, mitochondrial RNA, plasmid DNA, messenger RNA and nuclear DNA. It is also possible to select as target molecules nucleic acid from the above

In a preferred embodiment, a method provided by the invention uses as a target for in said hybridisation a 16S ribosomal RNA molecule. In a particular embodiment of the invention said probe is having no more than five, preferably no more than two mismatches with a probe selected of a group composed of probes having a sequence GCCTGCCAGTTTTGGAATC or GTAGCGCTACTCGTAAGG or GAGCAAAGGTATTAACTTTACTCCC or GTTAGCCGTCGTTTGTGG or TTATGCGCCTCTGTATGGG or AGAGAAGCAAGCTTCTCGTCG or GCCACTCCTCTTTTTCCGG or GCTAATGCAGCGCGATT or CCGAAGGGCAAGCCTCTA or AGAGAAGCAAGCTTCTCGTCGTT, each selected in relation to a method as provided by the invention or in relation to congruent antibiotic sensitivity of a bacterium recognised by said probe.

In addition, a method is provided by the invention that is further comprising hybridising said sample with at least one positive control probe capable of hybridising with nucleic acid found in a majority of bacterial species and/or with at least one negative control probe not being capable of hybridising with nucleic acid found in a majority of bacterial species. Preferably said majority comprises at least 90% of bacterial species, especially with those species found in general with possibly infected (septicaemic) patients. A method as provided by the invention is even more specific and/or sensitive when at least 95%, preferably at least 99% of said species is reactive with said positive control probe or no more than 5%, preferably no more than 1% is reactive with said negative control probe.

Such a positive or negative control probe as provided by the invention is given in the experimental part, in general said positive control probe comprises no more than five mismatches with a probe with the sequence

Furthermore, the invention provides a method with additional value to the clinician in that in said method a probe is selected for its reactivity with one or a group of bacterial genera and or (sub)species having congruent susceptibility to antibiotic treatment. Such a probe detecting or identifying a bacterium in a sample, preferably a clinical sample, is capable of hybridising with nucleic acid found in a group of bacterial genera and/or species or subspecies such as found with Staphylococcus and many other bacteria having congruent susceptibility to antibiotic treatment.

In a preferred embodiment of the invention, such a probe is having no more than five, preferably no more than two mismatches with a probe selected of a group composed of probes having a sequence GCCTGCCAGTTTCGAATG or GAGCAAAGGTATTAACTTTACTCCC (i.e. reactive with bacteria for which amoxycillin treatment is most likely effective) or GTAGCCCTACTCGTAAGG (cephalosporin treatment) or GTTAGCCGTCCCTTTCTGG (piperacillin and/or aminoglycoside) or TTATCCCCCTCTGATGGG or GCCACTCCTCTTTTTCCGG (amoxycillin) or GCTAATGCAGCGCGGATCC or CCGAAGGGGAAGGCTCTA (vancomycin) or AGAGAAGCAAGCTTCTCGTCCGTT or AGAGAAGCAAGCTTCTCGTCCG (flucloxacillin).

In a much preferred embodiment of the invention a one-step procedure is used for both binding target bacteria (in the sample) to a microscopic slide and fixing intracellular structures. In the experimental part, various lysis buffers and fixating technique are provided that utilise such a one-step procedure.

Furthermore, the invention provides a diagnostic test kit comprising means for detecting or identifying a bacterium suspected of being present in a sample using a method according to the invention or using a probe

instructions for a method comprising in situ hybridisation may be added. Optionally, said probes, which can be common nucleic acid or peptide nucleic acid probes, are linked to reporter molecules such as direct fluorescent labels. Other reporter molecules, such as enzyme- or radioactive labels are also known.

In addition, said kit may comprise one or more of the necessary buffer solutions, such as lysis buffer or hybridisation, optionally in ready made form, or for example cover slips and reaction vials. Said kit may fully comprise sets of probes reactive with a wide gamut of (pathogenic) bacteria, optionally characterised by reactivity with bacteria of congruent antibiotic susceptibility, or may comprise sets of probes specifically directed against bacteria of Gram-positve of -negative, rod, coccus or chain- or clump-like character.

Such a kit may also comprise probes specifically reactive with antibiotic resistance genes, providing a positive identification of least applicable antibiotic treatment.

The invention is further explained in the experimental part of the description which is not limiting the invention.

Experimental part

An example of a set of probes specific for the detection of pathogenic bacteria and an example of a new protocol for high-speed in situ hybridisation are presented. The methodology described here can for example used for both a preliminary screening of samples from septicaemic patients or as a full substitute on the basis [illegible] decisions are made. The invention

[illegible] samp[illegible]

comprising

A set of fluorescently labelled oligonucleotide probes designed to hybridize specifically with a group of pathogenic bacteria (i.e. genus-specific probes) or with one specific pathogen (i.e. species-specific probe) or with bacteria with congruent susceptibility or resistance to antibiotics.

A protocol for fast in situ hybridization of bacteria present in samples of blood collected from septicaemic patients, using the said probes.

Oligonucleotide probes designed to hybridize specifically with a group of pathogenic bacteria.

In a particular embodiment of the invention a method provided by the invention is exemplified by making use of 16S rRNA target molecule because a large databank containing 16S rRNA-sequences exists and is freely accessible via the Internet. Labeled probes form an essential part in *in situ* hybridizations. The present invention provides a set of probes which have been designed in an unexpected novel manner i.e. not based on normal taxonomic principles but rather on their pathological significance. The group of probes which apply to this particular embodiment of the invention have been designed in such a way that they span group(s) of bacteria which are clustered on the basis of presumed congruent sensitivity to antimicrobial agents. Positive identification thus yields direct therapeutic information. Grouping bacteria on the basis of their presumed antibiotic susceptibility results in groups of bacteria [illegible] of different species.

on the criteria of presumed antibiotic susceptibility patterns is much faster than classical cultivation methods that still suffer from lengthy variability induced by environmental factors. The probes are preferably labelled with enzymatic or fluorescent labels. Current fluorescent labels which are applicable in this invention are:

1) Direct fluorescent labels:
- Fluorescein-isothiocyanate (FITC)
- Tetramethylrhodamine-5-isothiocyanate (TRITC)
- Texasred™
- 5(6)-carboxyfluorescein-N-hydroxysuccimide-ester (FLUOS™)
- 7-amino-4-methylcoumarin-3-acetic acid (AMCA™)
- Phycoerythrin
- Indocarbocyanine dyes such as Cy3™, Cy5™ and C7™
- Any other direct fluorescent label

2) Indirect fluorescent labels:
- Enzymes such as alkaline phosphatase or horseradishperoxidase either attached directly or via a C6-thiol linker and used in combination with chemiluminescent substrates like AMPPD (3-('spiroadmantane)-4-methoxy-4-(3'-phosphoryloxy)-phenyl-1,2-dioxethane) or fluorescence generating substrates.
- Digoxigenin (DIG) in combination with anti-DIG antibodies labeled with:
  - gold particles
  - fluorescent labels
  - Enzymes such as alkaline phosphatase or horseradish peroxidase, optionally in combination with chemiluminescent substrates like AMPPD (3-('spiroadmantane)-4-methoxy-4-(3'-phospho- ryloxy)-phenyl-1,2-dioxethane) or fluorescence generating substrates.
- Biotin in combination with enzyme [illegible]

- Dinitrophenyl as hapten in combination with appropriate antibodies and labeled anti-like the anti-DIG antibodies
- Any other indirect fluorescent or enzymatic label

Fluorescent labels allow direct microscopic analysis preferably combined with image analysis. For the detection of fluorescent oligonucleotide probes hybridised to ribosomal RNA of the target bacterium, photography can be applied. However quantitation by this method is hampered by the absence of objective criteria by means of which discrimination between hybridized and non-hybridized cells can be performed. Therefore for objective evaluation of probe-specificity, an image analysis system is employed which allows fluorimetrical reading of individual bacterial cells.

A protocol for fast *in situ* hybridization of bacteria present in samples of blood

Protocols for the detection of rRNA *in situ* typically utilise both a lytic reagent for permeabilisation of the bacterial cell wall and fixatives to preserve structural and molecular integrity of cellular components. However, the results of such hybridizations are highly dependent on the type, concentration and incubation-time of both the lytic reagent and the fixative. Component 2 of the invention consists of a protocol for *in situ* hybridization in which both permeabilisation and fixation have been optimized for a subsequent hybridisation of maximally 2 hours. For this protocol it was important to ensure that the hybridization procedure used was applicable to a wide variety of unidentified bacteria. Differentiated use of lytic reagents could only be based on information obtained from direct Gram-staining of the pre-cultured blood

A optimal lytic reagent can be chosen on the basis of the gram-stain of the pathogen present in the sample of blood. This procedure of differentiated permeabilisation is novel to regular protocols for in situ hybridisation in which the permeabilisation is always dedicated to the permeabilisation of one or a defined group of target bacteria. In this new procedure a very wide array of unidentified bacteria can sufficiently be permeabilised without destruction of intracellular structures.

A one-step procedure is used for both binding target bacteria (in the sample) to the microscopic slide and fixing intracellular structures. Procedures presented in the current scientific literature all use multi-step protocols for binding, fixing and dehydration of the bacterial cells in order to condition them for optimal hybridisation.

The hybridisation time is shortened to 2 hours. Regular protocols for *in situ* hybridisation utilise a hybridisation time of minimally 24 hours, rendering them useless for rapid diagnostic applications.

The invention also provides kits for carrying out the rapid detection of bacteria in blood samples according to the invention. Such a kit will usually comprise at least a probe or probes and optionally other reagents such as components for hybridisation-fluid, washing-fluid and permeabilisation-fluid.

Such a kit may be applied in a routine bacteriology laboratory or in a bedside environment, both as a fast screening method or as a full substitute for classical identification methods.

Examples of probe design and development

are found in blood from septicaemic patients. In addition each probe hybridises with a spectrum of a number of bacteria which share coherent (but often not identical) antibiotic sensitivity patterns

Protocol example.

A newly devised protocol for fast in-situ hybridization of pathogens in blood from septicaemic patients. This version consists of a step-wise version which can directly be used in a laboratory environment.

1 Collect a sample of blood from a patient using a vacuum sealed culture bottle.

2 Place the culture bottle in the pre-culturing machine (e.g. BactAlert, Organon Teknika, Durham, NC 27704) to monitor the growth of the pathogen. On-line

3 After bacterial growth in a sample of blood has been detected, perform a Gram-stain and take out the culture bottle and collect 1 ml. of blood from the bottle using a syringe.

4 Using the syringe, put +/- 0.1 ml of this sample on a degreased glass slide. And streak out using a slide of glass.

5 Dry the slide for 5 minutes on a hotplate (for example of approximately 50°C).

6 Fix during 5 min. in ethanol(96%):formaldehyde 37% (9:1.)

7 Dry the slide for 5 minutes on a hotplate. (Slides can be stored for several months if kept at room temperature in a dry chamber)

8 Permeabilise **Streptococci** 20 min at 25 C with lysozyme (1 g/l)

9 Permeabilise **Staphylococci** 20 min at 25 C with Lysostaphin (100 units/ml)

10 Rinse the slide with (demineralised) water for 5 minutes

11 Dry the slide for 5 minutes on a hotplate.

12 Pipet hybridisation buffer(+SDS)-probe mix ([probe]=10ng/µl). Cover with a coverslip.

13 Hybridize 2 hours (for example at 46°C).

14 Rinse 5 min using hybridisation buffer(-SDS).

15 Mount the slide with a coverslip.

16 Evaluate the slide.

Phosphate buffered saline

- 8 g/l NaCl
- 0.2 g/l KCl
- 1.44 g/l Na_2HPO_4
- 0.24 g/l KH_2PO_4

Hybridisation buffer (+SDS)
- 900 ml Milli-Q water
- 58.6 g NaCl
- 1.52 g Tris (hydroxymethyl-aminomethane)
- adjust to pH 7.8
- add 990 ml water
- sterilize 15 minutes
- 10 ml SDS (10%) added

hybridisation buffer (-SDS)
- 900 ml Milli-Q water
- 58,6 g NaCl
- 1,52 g Tris
- adjust to pH 7.8
- 100 ml Milli-Q water
- sterilize 15 minutes

hybridisation buffer-probe mix
- 10 ng/ul of lyophilized probe in hybridisation buffer

lysozyme buffer
- 1,2 g Tris (=100mM)
- 1,86 g EDTA (=50mM)
- add 100 ml of milli-Q
- adjust to pH 7.5
- 0,05 to 0,2 g lysozyme

Lysostaphin buffer
- 1,2 g Tris (=100mM)
- 1,86 g EDTA (=50mM)
- add 100 ml of milli-Q
- adjust to pH 7.5
- 0,05 to 0,2 g lysostaphin
- dilute a lysostaphin (1 mg/ml) in Milli-Q

Optionally, 1 lysozyme buffer (1 lysostaphin buffer) is to 1,2 mg/ml Proteinase K is added.

ethanol-formaldehyde (9:1)
- 1 ml formaldehyde 37%
- 9 ml ethanol 96%

Validation of probe specificity

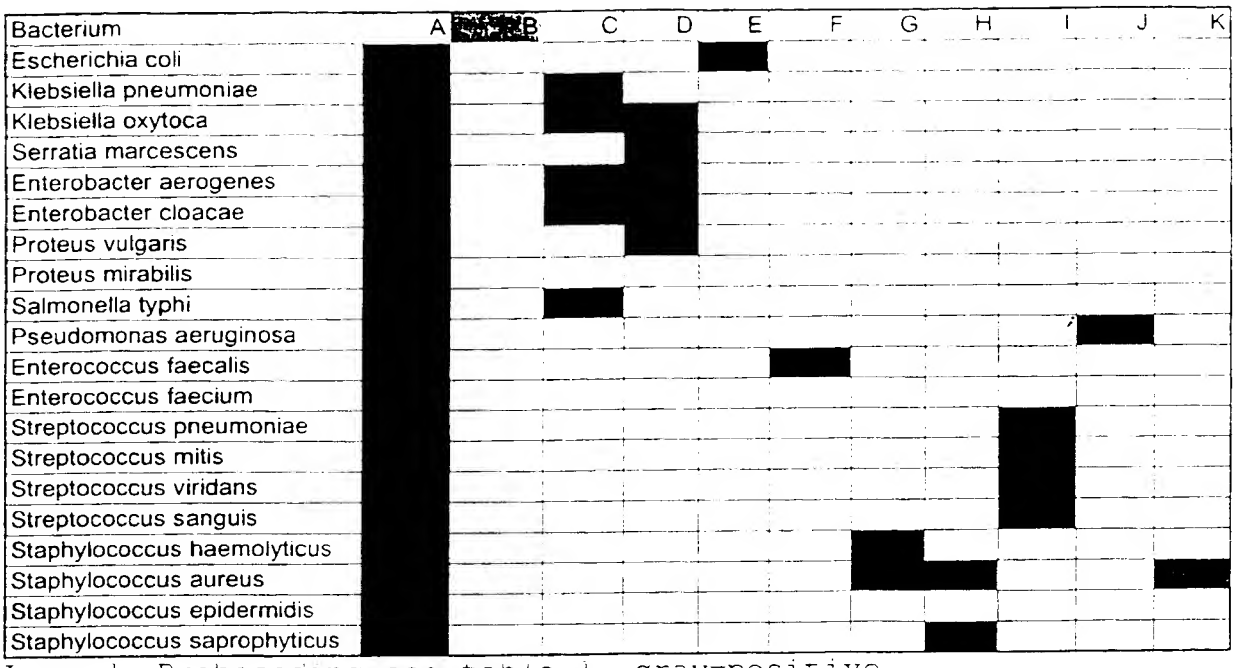
Specificity of probes was tested against the complete RDA-database (http://rdpwww.life.uiuc.edu:80/rdphome.html) of 15 august 1996 using the CheckProbe command and was considered sufficient if a no more than five, preferably no more than two mismatches were observed. Furthermore, to determine whether the probes could reach their specific target sequence, a reference collection of 20 of the most predominant bacteria in sepsis were hybridised using both the protocol and the probes mentioned here above. The result of this validation is listed in table 2. As can be read from this table all probes yield a satisfying hybridisation profile. Using the group-probes C and D it is possible to distinguish between: four groups of gram-negative rods:
C-positive and D-positive: Klebsiella oxytoca, Enterobacter cloacae and Enterobacter aerogenes
C-positive and D-negative: Klebsiella pneumoniae and Salmonella typhi
C-negative and D-positive: Serratia marcescens and Proteus vulgaris
C-negative and D-negative: Proteus mirabilis.
For Escherichia coli and Pseudomonas aeruginosa two species-specific probes (E and F) have been designed and validated. These probes are optionally included because both Escherichia and Pseudomonas are notorious pathogens

notorious pathogen. Probe I is a genus-specific probe which can be used in conjunction with probe F because Streptococci and Enterococci share the same morphology, while they require different antimicrobial treatment. Using both probes G and H, 4 separate species of Staphylococci can be distinguished:

G-positive and H-positive: Staphylococcus aureus
G-positive and H-negative: Staphylococcus haemolyticus
G-negative and H-positive: Staphylococcus saprophyticus
G-negative and H-negative: Staphylococcus epidermidis

Probe K is a *species*-specific-probe for Staphylococcus aureus and can be used to support the results obtained by probes G and H.

Table 2.



Legend: Probecoding see table 1, gray=positive hybridization, white=no hybridization

Testing a method in whole-blood samples.

Preliminary testing of a new method in 50 whole blood samples which were found positive upon pre-culturing yielded a correlation of 96% between a method described here and the classical culturing method which was also applied to each of the 50 samples.

However, the results of a method described here could be obtained within 3 hours while culturing results took a mean analysis-time of 32 hours.

Further practical application

Septicemia is a pathological condition in which viable and multiplying bacteria may be present in the bloodstream. This condition may occur after trauma or surgery (especially of the visceral organs), immunosuppression and obstetrical complications. It is a potential life-threatening condition and appropriate information on the

is routinely carried out by selective culturing of blood, which has previously been incubated in a general medium in a blood culture system. Currently, three continuous-reading, automated and computed blood culture systems are available in clinical microbiology today: the BacTec 9240 (Becton Dickinson Instruments), the BacT Alert 3D (Organon Teknika) and the Extra Sensing Power (Difco Laboratories). All of these machines measure the production-rate of a bacterium specific metabolite in the culture-bottle containing the patient's blood supplemented with general nutrient broth. Subsequently if bacterial metabolic activity is detected, the positive blood culture sample is plated on appropriate selective media for further analysis. Microbial identification, taking the positive blood culture as a starting point, takes 24 h to 72 h to complete. Reduction of the analysis time may result in reduction of the use of broad-spectrum antibiotics as the genus or species of a pathogen gives an indirect indication of the most appropriate antibiotic. Subsequently, this may result in a lower frequency of emergence of resistance against broad-spectrum antibiotics. Furthermore, it may result in lower cost because suppressive empiric therapy may be substituted by tailored and less expensive antibiotics with a smaller spectrum. Several methods for rapid detection of pathogens in human blood have been described previously, most of them using the polymerase chain reaction or fluorescently labeled probes. Although these methods are fast and accurate, routine bacteriological analysis still heavily relies on classical culturing technique. It was therefore decided that for a molecular biological method to be successfully implemented in routine bacteriology it should be fast (maximally 1-4 h) and very easy-to-use (i.e. as complex as the preparation of a Gram-stained slide). A

oligonucleotide probes, was developed and validated. The probes described in this further practical application section comprise 21 single strain oligonucleotides labelled with fluorescein isothiocyanate at the 5'end; complementary to a genus- or species-specific sequence on the 16S- or the 23S ribosomal RNA of the target-organism.

Materials and methods

Blood samples

During the time of this study a total of 181 blood samples which tested positive in the BactAlert-blood culture machine were processed simultaneously, using both whole-cell hybridization and accepted culturing methods.

Culturing

Microorganisms cultivated from positive blood cultures were identified by using the API-testsystem (BioMerieux, France) or by using standard microbiological methods.

Probes

The characteristics of the probes used in this study are listed in Table 3. All probes consist of a single stranded oligonucleotide sequence covalently linked with fluorescein isothiocyanate at the 5'end. Probes were synthesized by Eurogentec BV (Maastricht, The Netherlands).

Table 3. Oligonucleotide probes used for hybridization of some pathogens normally detected in blood from septic patients

Probe*	Sequence (5'-->3')	Target(s)	Preferred antibiotic**
EUB	GCTGCTTCCCGTAGGAGT	Bacterial Kingdom	n.a.***
non-EUB	ACTCCTACGGGAGGCAGC	negative control	n.a.
STREP	GTTAGCCGTCCCTTTCTGG	*Streptococcus* spp.	Penicillin G
EFAEC	TTATGCCCCTCTGATGGG	*Enterococcus faecalis*	Amoxycillin
EFAEM	GCCACTCCTCTTTTTCCGG	*Enterococcus faecium*	Vancomycin
STAUR	AGAGAACAAGCTTCTCGTCCG	*Staphylococcus aureus*	Flucloxacillin
CNS	CGACGGCTAGCTCCAAATGGTTACT	Coagulase-negative Staphylococci	Vancomycin
ECOLI	GCAAAGGTATTAACTTTACTCCC	*Escherichia coli*	Amoxycillin
PSEUDAER	GGACGTTATCCCCCACTAT	*Pseudomonas aeruginosa*	Piperacillin+ aminoglycoside
ENTBAC	CATCAATCACAAAGTGGTAAGCGCC	*Enterobacterium spp*	2nd generation cephalosporin

* All probes consist of single strain DNA covalently linked with flurorescein iso-thyocyanate at the 5'-end. The *E. coli*-specific probe is directed against 23S rRNA, the other probes are directed against the 16S rRNA. Probe-nomenclature consists of mnemonics instead of a formal nomenclature-system for reasons of convenience.

** The antibiotic of first choice

*** not applicable

**** Limited choice from all available therapeutics. On the basis of the local epidemiological situations other therapeutics may prevail

Whole cell hybridization

After gramstaining a streak-out preparation of a positive blood culture, a choice was made in the subsequent permeabilization-protocol and a set of appropriate probes (Table 3). Grampositive streptococci were permeabilized by incubating the fixed slide in a permeabilization-buffer (1 mg/ml lysozym) during 5 min., gram-positive staphylococci

during 30 min. Gram-negative rods were not permeabilized. Other gram-morphologies were not considered in this section because of the low incidence of these groups of bacteria in septicemia. From a positive blood culture fifteen µl was pipetted on a glass slide and subsequently streaked out. After air-drying the slide, the cells on the slide were fixed in a 4% formaldehyde-solution in pure ethanol. After permeabilization, the cells on the slide were hybridized at 50°C. Gram-negative rods were hybridized during 45 min., gram-positive staphylococci were hybridized during 2 h and gram-positive streptococci were hybridized during 5 min. Per gram-type a different set of probes was chosen (see Table 4).

Table 4 Performance of the method

Application-criterion*	Probe	Target organism	n**	r***
Each assay	EUB	All bacteria	1[illegible]	1.0
	non-EUB	negative control	1[illegible]	1
Gram-positive chain	STREP	*Streptococcus spp.*	2[illegible]	1
	EFAEC	*Enterococcus faecalis*	1[illegible]	1.0
	EFAEM	*Enterococcus faecium*	7	1.0
Gram-positive clumps	STAUR	*Staphylococcus Aureus*	1[illegible]	1.0****
	CNS	Coagulase-negative Staphylococci	7[illegible]	1.0
Gram-negative rods	ECOLI	*Escherichia coli*	2[illegible]	1.0
	PSEUDAER	*Pseudomonas aeruginosa*	4	1.0
	ENTBAC	*Enterobacteriaceae spp.*	2[illegible]	1.0

* The application criterion is the micromorphology of the pathogen in the initial gram-stain which is made after the BactAlert blood culture machine has detected microbolic activity in the bloodsample

** n=number of strains positively identified by culturing

*** r=correlation coefficient. This is the number of matching identifications between FISH and traditional culturing divided by the total number of assays

**** Comprises of 66% of the total number of samples tested. Other samples showed no signal with the positive control probe

However, a probe (i.e. EUB-probe) positive for almost all bacteria and the reverse complementary probe (i.e. non-EUB probe) were included as a positive and negative control respectively, irrespective of the gram-type. Prior to use, probes were diluted to a concentration of 10 ng/ml in hybridization-buffer (20 mM Tris-HCl, 0.9M NaCl, 0.1% SDS, pH 7.2). After hybridization, the slides were rinsed during 15 min. at 48°C in washing buffer (20 mM Tris-HCl, 0.9M NaCl, 0.1% SDS, pH 7.2) and mounted with VectaShield (Vector Laboratories, Burlinghame, USA). Immediately hereafter, the slides were evaluated using an epifluorescence microscope.

The results of this section show that identification using whole-cell hybridization substantially increased the speed of the diagnosis. In figure 1 a typical example of the microscopic image obtained after hybridizing a blood sample obtained from a patient suffering from *Streptococcus pneumoniae* sepsis using the STREP-probe is shown. Using the described protocol, a clear-cut positive signal was obtained. Repeated microscopic evaluation by different observers confirmed the unambiguity of the interpretation of the images obtained by this method. In Table 4, the results of the study are listed. The observation that all strains hybridize positively with the EUB-probe indicates that the hybridization protocol is applicable for whole cell hybridization of the bacterial species and genera tested in this study. The negative results obtained with the non-EUB probe indicate the absence of aspecific interaction between the probe and constituents of the cellular matrix. The speed of diagnosis (after the sample is positive in the BactAlert blood culture machine) varies between 25 min (streptococci/enterococci) and 2 h (staphylococci), while routine bacteriological determination would take at least 24 h to 48 h. The advantage to the patient is obvious because, as can be read from Table 3, the clinician is able to start appropriate antimicrobial therapy within the working day instead of after 24 h to 48 h. Being able to choose the most appropriate antibiotic also diminishes the need for broad-spectrum antibiotics therewith indirectly lowering the incidence of antibiotic-resistance. In table 4 the results obtained in this section are mentioned.

Broader application of the product

In its current form the product can be used in fast in

other clinical samples. Experiments using the current product (i.e. probes and protocol) in another type of clinical sample have been carried out. The sample-types were: liquor and ascites. Results indicate that application of the product in these samples is perfectly well possible. Future application include:

- New probes for other relevant species/genera
- Other types of clinical samples like: sputum, pus, urine, where generally non-septicaemic bacteria, such as Legionella pneumoniae can be found, using a method according to the invention.

Advantages of whole-cell hybridization

- Rapid diagnosis enabling the clinician to easily choose the appropriate antibiotic
- Less use of broad spectrum antibiotics, therewith lowering the incidence of antibiotic resistance
- Cheap, a typical FISH-analysis is about 50% cheaper than a traditional culturing-based analysis.
- Easy to perform. A FISH-based analysis requires less actions and less hands-on time than a gram stain

Lay-out of kits

There are many possibilities for possible kit formats, several are listed below.
One main kit for 10 tests (1 test is 1 positive control, 1 negative control and one unknown) consisting of all kits 1-4 listed below including a detailed protocol. Or the kits listed below alone or in a combination.

Kit 1 (the control kit):

- Lyophilized positive control probe such as EUB or probe(s) functionally related thereto
- Lyophilized negative control probe such as non-EUB or probe(s) functionally related thereto
- Lyophilized hybridization buffer (20 mM Tris-HCl, 0.9M NaCl, 0.1% SDS, pH 7.2)

Kit 2 for gram-negative samples:

- Lyophilized probe such as ECOLI, PSEUDAER, ENTBAC or probe(s) functionally related thereto
- Lyophilized hybridization buffer (20 mM Tris-HCl, 0.9M NaCl, 0.1% SDS, pH 7.2)

Kit 3 for gram-positive streptococci-like bacteria:

- Lyophilized probes such as STREP, EFAEC, EFAEM or probe(s) functionally related thereto
- Lyophilized hybridization buffer (20 mM Tris-HCl, 0.9M NaCL, 0.1% SDS, pH 7.2) with 1 mg/ml hen-eggwhite lysozyme.

Kit 4 for staphylococci-like bacteria:

- Lyophilized probes such as STAUR, CNS or probe(s) functionally related thereto
- Lyophilized hybridization buffer (20 mM Tris-HCl, 0.9M NaCl, 0.1% SDS, pH 7.2) with 1 units/ml lysostaphin

Basic labeling of probes is with fluorescein iso-thio cyanate. Alternatively kits may contain probes with other fluorescent labels e.g. Cy-3, Cy-5, Texas-Red, Rhodamine

with different fluorescent labels for simultaneous detection of different targets with one test. We have successfully detected streptococci and enterococci in one sample in this way. In Fig 2 an example of this type of application is shown. Here, a mixed infection of morphologically indistinguishable gram-positive streptococcus-like bacteria are successfully hybridized with both the STREP-probe (FITC-label) and the EFAEC-probe (Cy3-label). Other combinations of the above kits may also be provided as one kit for a specific application.

Legends

Figure 1: Cells of *Streptococcus pneumoniae* show intense bright fluorescence after 1 min. of incubation with the STREP-probe at 55°C. Magnification = 1,000x, fluorochrome = fluorescein isothiocyanate

Figure 2: Mixed infection with *E. faecalis* and *S. pneumoniae* hybridized simultaneously with both the STREP-probe (FITC-label) and the EFAECAL-probe (Cy3-label). Also a fluorescent DNA/RNA stain (DAPI) has been applied to detect all nucleic acid.

CLAIMS

1. A method for determining a bacterium suspected of being present in a sample comprising
a. testing said sample by Gram-staining and
b. testing said sample with a probe according to an in situ hybridisation protocol selected on the basis of the outcome of said Gram-staining.

2. A method according to claim 1 wherein said sample is a clinical sample.

3. A method according to claim 2 wherein said sample is mammalian blood, preferably being derived from a human.

4. A method according to claim 1, 2 or 3 wherein said Gram-staining indicates the presence of a Gram-negative bacterium in said sample, further comprising determining the rod or coccus character of said bacterium.

5. A method according to claim 4 wherein said character is of the rod type, further comprising hybridising said sample with at least one probe selected from a group of probes capable of hybridising with nucleic acid found in *Escherichia coli*, in *Klebsiella pneumoniae*, in *Klebsiella oxytoca*, in *Serratia marcescens*, in *Enterobacter aerogenes*, in *Enterobacter cloacae*, in *Proteus vulgaris*, in *Proteus mirabilis*, in *Salmonella typhi*, in *Pseudomonas aeruginosa*.

6. A method according to claim 5 wherein said nucleic acid is ribosomal RNA.

7. A method according to claim 6 wherein said probe is having no more than two, preferably no more than one mismatches with a probe selected of a group composed of probes having a sequence GCCTCCCAGTTTCGAATC or GTAGGGGTACTCGTAAGG or GAAAAAGCTATTAACTTTACTCCC or

sample to treatment with a lysis buffer comprising lysozyme.

9. A method according to claim 1, 2 or 3 wherein said Gram-staining indicates the presence of a Gram-positive bacterium in said sample, further comprising determining the rod or coccus character of said bacterium.

10. A method according to claim 9 wherein said character is of the rod type, further comprising subjecting said sample to treatment with a lysis buffer comprising lysozyme and/or Proteinase K.

11. A method according to claim 9 wherein said character is of the coccus type, further comprising determining a chain-like or clump-like character of said bacteria.

12. A method according to claim 11 wherein said character is chain-like, further comprising subjecting said sample to treatment with a lysis buffer comprising lysozyme.

13. A method according to claim 12 further comprising hybridising said sample with at least one probe selected from a group of probes capable of hybridising with nucleic acid found in *Enterococcus faecalis*, in *Streptococcus pneumoniae*, in *Streptococcus mitis*, in *Streptococcus viridans*, in *Streptococcus sanguis*, in *Enterococcus faecium*.

14. A method according to claim 13 wherein said nucleic acid is ribosomal RNA.

15. A method according to claim 14 wherein said probe is having no more than five, preferably no more than two mismatches with a probe selected of a group composed of probes having a sequence TTATGCCCGTCTGATCCA or AGAGAAGCAAGCTTCTCGTCCG or GCCAGTGCTCTTTTTGCGG.

16. A method according to claim 11 wherein said character is clump-like, further comprising subjecting said sample to treatment with a lysis buffer comprising lysostaphin and/or Proteinase K.

from a group of probes capable of hybridising with nucleic acid found in Staphylococcus aureus, in Staphylococcus haemolyticus, in Staphylococcus saprophyticus.

18. A method according to claim 17 wherein said nucleic acid is ribosomal RNA.

19. A method according to claim 18 wherein said probe is having no more than five, preferably no more than two mismatches with a probe selected of a group composed of probes having a sequence GCTAATGCAGCGCGGATCC or CCGAAGGGGAAGGCTCTA or AGAGAAGCAAGCTTCTCGTCCGTT.

20. A method according to any of claims 4 to 19 further comprising hybridising said sample with at least one positive control probe and/or with at least one negative control probe.

21. A method according to claim 20 wherein said positive control probe comprises no more than five mismatches with a probe with the sequence GCTGCCTCCCGTAGGAGT and/or wherein said negative control probe comprises no more than five mismatches with a probe with the sequence ACTCCTACGGGAGGCAGC.

22. A method according to anyone of claims 1 to 21 further comprising a one-step procedure to bind bacteria present in said sample to a microscopic slide and simultaneously fix intracellular structures.

23. A method according to anyone of claims 1 to 22 wherein said probe is selected for its reactivity with one or a group of bacterial genera and/or species having congruent susceptibility to antibiotic treatment.

24. A probe detecting or identifying a bacterium in a sample, preferably a clinical sample, said probe capable of hybridising with nucleic acid found in a group of bacterial genera and/or species having congruent susceptibility to antibiotic treatment.

25. A probe according to claim 24 wherein said probe is

probes having a sequence GCCTGCCAGTTTCGAATC or GTAGCGCTACTCGTAAGG or GAGCAAAGGTATTAACTTTACTCCC or GTTAGCCGTCCCTTTCTGG or TTATCCCCCTCTGATGGG or AGAGAAGCAAGCTTCTCGTCCG or GCCACTCCTCTTTTTCCGG or GCTAATGCAGCGCGGATCC or CCGAAGGGGAAGGCTCTA or AGAGAAGCAAGCTTCTCGTCCGTT.

26. A diagnostic test kit comprising means for detecting or identifying a bacterium suspected of being present in a sample using a method according to anyone of claims 1 to 23 or using a probe according to claim 24 or 25.
